(54) Title: FLASH UNIT FOR DIGITAL 3D PHOTOGRAPHY

## (57) Abstract

A flash unit comprising a flash light source (2) and a projector lens (8) positioned to project light from the flash source onto a subject. In a preferred embodiment there are two flash light sources for projecting patterned and unpatterned light respectively on to the subject, and a circuit is provided to trigger the two flash sources with a predetermined time interval therebetween.

1 FLASH UNIT FOR DIGITAL 3D PHOTOGRAPHY

2

3 This invention relates to the field of three-  
4 dimensional digital image capture, and more  
5 particularly three dimensional image capture of people  
6 using digital stereo photogrammetry. Digital stereo  
7 photogrammetry is a technique for the recovery of the  
8 three-dimensional attributes of an object by the use of  
9 pairs of digital photographs, typically, but not  
10 necessarily, taken by a pair of cameras. Provided that  
11 the positions, orientations and focal properties of the  
12 cameras used to take the images are known, it is  
13 possible for a computer to estimate the distance  
14 between either of the cameras and an object appearing  
15 in the images taken by both of them.

16

17 The computer does this by determining which group of  
18 contiguous pixels in an image taken with the second  
19 camera match up with a pre-specified group of  
20 contiguous pixels in an image taken with the first  
21 camera. From this, a parallax can be computed, and from  
22 that, using simple geometry, the distance to the  
23 object, light from which produced these pixels, can be  
24 derived.

1 The ability of a computer to correctly match  
2 corresponding areas of the images from the two cameras  
3 is dependent upon there existing, within each area,  
4 significant variations in image intensity. If an area  
5 of an object is visually 'flat', that is to say, of  
6 uniform visual intensity, then there will be potential  
7 for ambiguity in determining the position of matching  
8 points on the two images. Such visual flatness normally  
9 arises because an object or subject being imaged is lit  
10 by a uniform source of illumination and has areas on  
11 their surface or on their skin which differ little in  
12 albedo.

13  
14 In principle the uniformity of image intensity can be  
15 obviated in two ways. One can change the albedo of the  
16 surface, for example by painting patterns with make-up  
17 on a person's face, or alternatively, one can vary the  
18 intensity of illumination across the surfaces being  
19 imaged.

20  
21 For certain applications it is convenient to capture  
22 both the three-dimensional shape of an object and its  
23 associated visual texture, for instance when capturing  
24 both the appearance and three-dimensional shape of an  
25 actor's face. This makes the use of visually disruptive  
26 makeup unattractive. The alternative of illuminating  
27 the subject with textured light is used in known  
28 systems such as the Turing C3D system.

29  
30 Drawbacks of the state of the art

31  
32 The state of the art technique for illuminating a  
33 subject with textured light involves the use of a slide  
34 projector which is set to produce a focused image of a

1 random dot pattern on the face of the subject. The  
2 process involves taking an initial pair of images using  
3 textured light, a subsequent third image is then taken  
4 with the slide projector illuminating the subject  
5 through a uniform gray slide. The third image, having  
6 been taken using uniform light intensity can be used to  
7 reconstruct the subject's skin tone in the ultimate  
8 computerised three-dimensional model.

9  
10 Whilst this approach produces reasonably good three-  
11 dimensional models it does suffer from a number of  
12 practical disadvantages. One of these is that the  
13 subject has to stare into a bright light coming from  
14 the projector. To allow for sufficient depth of field  
15 the aperture of the projector must of necessity be  
16 small. Intense illumination subtending a small angle of  
17 the field of view of the eye has recently been brought  
18 under various international health and safety  
19 regulations which render the legality of such a system  
20 questionable. Whether safe or not the experience of  
21 staring into an intense light is unpleasant for the  
22 subject and does not facilitate the capture of natural  
23 and relaxed expressions.

24  
25 Since the duration of the exposure is not well  
26 controlled, there is a danger that the infra-red  
27 loading on the retina from the high intensity lamp in  
28 the slide projector may exceed safe limits. A second  
29 drawback is the imperfect registration between the  
30 textured and white light images consequent upon slight  
31 movements by the subject during the second or so that  
32 it takes to switch between textured and white slides. A  
33 third disadvantage relates to the bulk and power  
34 consumption of slide projectors. These are typically  
35 heavy devices requiring mains power for their  
36 operation. This precludes their being mounted on

1 photographic tripods, or being incorporated into a  
2 portable system.

3

4 The invention

5

6 This invention, which is defined in the appended  
7 claims, seeks to obviate the above disadvantages of the  
8 state of the art. It consists of a high depth of field  
9 flash projector, preferably batter powered. This has  
10 the advantages over a standard slide projector for  
11 three dimensional image capture of people using digital  
12 stereo photogrammetry that the energy delivered in a  
13 flash can be precisely calibrated and it is possible to  
14 ensure that this falls below a level that might pose a  
15 danger to the retina of the subject.

16

17 The intensity of light during the instant of the  
18 cameras exposure can be far greater than the intensity  
19 of a practical continuous light source even though the  
20 total energy delivered to the subject is substantially  
21 less than from a continuous source. This facilitates  
22 smaller apertures providing greater depth of field and  
23 also allows the projection optics to cover a wider  
24 angle than is practical with a continuous source. This  
25 means that the overall volume required for a three  
26 dimensional capture system and subject can be  
27 substantially reduced.

28

29 Because a high level of illumination only has to be  
30 maintained for a few milliseconds, power to the  
31 projector can be derived from a battery making the  
32 system portable.

33 The flash projector is light-weight and can be mounted  
34 on photographic tripods.

35

36 An embodiment of the invention is illustrated in the

1 drawings, in which:

2

3 Figure 1 is a perspective view of part of a flash  
4 unit forming one embodiment of the invention;

5

6 Figure 2 is an exploded view of the flash unit of  
7 Figure 1; and

8

9 Figure 3 is a block diagram of an auxiliary  
10 trigger mechanism which may be used in a  
11 modification of the embodiment.

12

13 The components are labelled in Fig 2 and are as  
14 follows:

15

16 1 Battery sub-assembly

17 2 Control electronics + flash tube

18 3 Housing with mounting points on the underside for  
19 fitting to standard photographic tripods

20 4 Holographic diffuser and fresnel lens

21 5 Mounting posts for bending the slide

22 6 Front block with curved rear edge to enforce a curve  
23 on the slide

24 7 Aperture disk

25 8 Lens

26 9 Lens Barrel

27

28 It is an objective of the design to achieve a high  
29 depth of field within which the projected texture is in  
30 focus on the face of the subject. This is achieved in  
31 the preferred embodiment by the use of:

32 An Aspheric doublet lens 8 which prevents chromatic  
33 aberration over the necessarily wide acceptance angle;  
34 an aperture of F 5 or greater;

35 and a curved slide. Curvature of the slide means that  
36 the relative focal distance between the centre of the

1 slide and the horizontal extremes can be reduced, thus  
2 increasing the depth of field over a wider area at  
3 short focal length.

4  
5 The slide is bent into position by hand and retained in  
6 place by the combination of the curvature on the rear  
7 edge of the front blocks and the posts 5 acting against  
8 the elasticity of the plastic slide case. This  
9 eliminates the need for any other slide retention  
10 mechanism and so reduces the cost of manufacture of the  
11 product. A standard 35mm plastic slide case is used.  
12 Preferably lithographic films or metal deposit on  
13 transparent substrates with a random dot pattern are  
14 inserted in the slide cases to ensure high contrast.

15  
16 The combination 4 of a holographic diffuser and a  
17 fresnel lens is a particularly suitable way of  
18 achieving uniform illumination of the slide, but other  
19 means may be used for this purpose.

20  
21 In a preferable extension to the design, additional  
22 control electronics capable of triggering an auxiliary  
23 un-textured flashgun as illustrated in Figure 3, are  
24 provided.

25  
26 The input signal to the flash unit is shown as *fire*,  
27 and the output from the auxiliary trigger mechanism are  
28 *firea* and *fireb*. *Firea* triggers the textured flash  
29 projector, *fireb* triggers an untextured flash gun.  
30 A reset input is also provided. The fire input is taken  
31 to the clock input of an edge triggered d type flip  
32 flop. The negated output of the flip flop is fed back  
33 into the flip flop, causing it to take on alternating 0  
34 and 1 values on successive rising edges of the clock  
35 signal. The output of the flipflop is directed to the  
36 select input of a 1 to 2 demultiplexer, whose data

1 input is provide by the original fire signal. The  
2 consequence is that alternate low going edges of fire  
3 pulses are directed to firea and fireb. If the two  
4 flash guns are designed to trigger on a low going pulse  
5 then the circuit is so arranged that successive fire  
6 impulses to the auxiliary trigger mechanism cause the  
7 textured and un-textured flash units to fire in  
8 alternation. This allows the subject to be illuminated  
9 with two flashes in quick succession, the first being  
10 textured and the second untextured or vice-versa.  
11 Cameras capture images for each flash. The delay  
12 between flashes can be arranged to be very short  
13 ensuring that only a minimal amount of movement by the  
14 subject can occur between capture of three-dimensional  
15 information (via the textured flash ) and capture of  
16 skin tones (via the un-textured flash).

17  
18 In a preferable extension to the design, the auxiliary  
19 trigger unit and the un-textured flash are incorporated  
20 with the flash projector into a single physical unit.

21  
22 An alternative embodiment would preferentially filter  
23 the textured flash to pass a wavelength blocked by a  
24 filter in the spectrum recorded by the camera used for  
25 the color information, while the stereo information was  
26 recorded by cameras suitably filtered to accept the  
27 wavelength of the textured flash. In a preferred  
28 embodiment of this type a notch-pass filter in the  
29 green portion of the visible spectrum would be used  
30 corresponding to a notch-blocking filter in the color  
31 recording camera. The color gamut of the color  
32 recording camera need not be significantly compromised  
33 by this notch since the color process of any color  
34 gamut requires interpolation of hue between the pass  
35 filters of the camera sensor.

36

1 The isolation between the texture flash pattern and the  
2 color record could be further enhanced by arranging  
3 that the texture flash and the un-textured flash for  
4 the color record were polarised at right angles, and  
5 providing suitable polarizing filters for the relevant  
6 cameras. This would not be able to isolate the two  
7 flashes by polarization alone as the skin would scatter  
8 and rotate the polarization angle to the extent that  
9 the isolation would be substantially reduced. However  
10 since very narrow color filters are expensive, a  
11 combination of relatively low cost polarization filters  
12 and broader band notch color filters may in some  
13 circumstances provide a substantial reduction in cost  
14 for the same effective isolation.

15  
16 While a pass filter beyond the visible spectrum is a  
17 possible alternative this embodiment is not preferred  
18 since the three-dimensional information would be  
19 compromised by the penetration through the skin of  
20 infra red light. The alternative of ultraviolet light  
21 has a very low reflectivity from skin and has the  
22 additional disadvantage of causing fluorescence in many  
23 clothing fabrics which may reduce the precision of the  
24 projected texture pattern and also cause the texture  
25 fluorescence to become visible to the color record.  
26 However, in the standard embodiment using the flip-flop  
27 mode, such fluorescence may in some circumstances, as  
28 for recording body parts where fabric was not present,  
29 be profitably exploited to enhance the contrast of the  
30 texture pattern on a subject by applying an invisible  
31 fluorescent makeup to the subject. This embodiment  
32 would require UV transparent optics to be used in the  
33 flash projector.

34  
35 It is frequently desirable to use a number of pairs of  
36 cameras, each pair with its own flash system. The

1 flash unit of the invention may be provided with a  
2 photosensor on its front face for slave operation in  
3 response to triggering of a first flash unit. Slave  
4 flash systems are known per se.

5

6

## 1     Claims

2

3     1.    A flash unit comprising a flash light source, and  
4           a projector lens positioned to project light from  
5           the flash source onto a subject.

6

7     2.    A flash unit according to Claim 1, in which the  
8           projector lens is dimensioned and positioned to  
9           give a depth of field of the same order of  
10          magnitude as a three-dimensional subject to be  
11          illuminated.

12

13    3.    A flash unit according to Claim 2, in which the  
14          projector lens has an aperture of F5 or greater.

15

16    4.    A flash unit according to Claim 2, or Claim 3, in  
17          which said depth of field approximates the depth  
18          of a human head.

19

20    5.    A flash unit according to any preceding Claim, in  
21          which means are provided to project a pattern onto  
22          the subject.

23

24    6.    A flash unit according to Claim 5, in which said  
25          means comprises a holder for a photographic  
26          transparency.

27

28    7.    A flash unit according to Claim 6, in which said  
29          holder is arranged to hold the transparency in a  
30          curve.

31

32    8.    A flash unit according to Claim 6 or Claim 7,  
33          including optical means for transmitting the flash  
34          light to the transparency as relatively uniform  
35          illumination across the area of the transparency.

36

- 1     9.    A flash unit according to Claim 8, in which said  
2           optical transmission means comprises a diffuser  
3           and a fresnel lens in series.  
4
- 5     10.   A flash unit according to Claim 9, in which the  
6           diffuser is a holographic diffuser.  
7
- 8     11.   A flash unit according to any of Claims 5 to 10,  
9           including a second flash source for projecting  
10          unpatterned light onto the subject.  
11
- 12    12.   A flash unit according to Claim 11, including  
13          circuit means for triggering the first and second  
14          flash sources with a predetermined time interval  
15          between them.  
16
- 17    13.   A flash unit according to Claim 12, in which said  
18          predetermined interval is of the order of  
19          milliseconds.  
20
- 21    14.   A flash unit according to claim 11, in which both  
22          flash sources operate simultaneously in  
23          cooperation with a pair of cameras, the flash unit  
24          including means to project patterned and  
25          unpatterned light in different spectral wavebands.  
26
- 27    15.   A flash unit according to claim 14 in combination  
28          with a pair of cameras, the second flash source  
29          being arranged to project substantially white  
30          light, the first flash source projecting  
31          substantially monochromatic (preferably infrared  
32          or ultraviolet) light, and one of the cameras  
33          being provided with a notch pass filter  
34          (optionally combined with a polarised filter) for  
35          said substantially monochromatic light.  
36

- 1      16. A flash unit according to any preceding claim,  
2      arranged as a readily portable unit including an  
3      internal battery pack.  
4
- 5      17. A method of capturing a digital 3-D representation  
6      of a 3-D object, which includes the steps of  
7      projecting upon the object first and second light  
8      flashes separated by a time interval, one of the  
9      light flashes being arranged to project a  
10     predetermined 2-D pattern in such a manner as to  
11     give a depth of field at the object of the same  
12     order of magnitude as the depth of the object, and  
13     the other light flash being unpatterned.  
14
- 15     18. The method of Claim 15, in which said time  
16     interval is of the order of milliseconds.  
17  
18
